Lab – Project-Builder.org

Lab Contents

This lab purpose is to install and use Project-Builder.org to produce packages for native and non-native Operating System, as well as experiencing the Continuous Packaging concept.

Lab Writer and Trainer

Bruno.Cornec@hp.com

Table of content

Overview of the Project–Builder.org Lab

Objectives

At the end of the Lab students should be able to install Project-Builder.org, use pb to create a new project, package it natively, inside a VM and/or a VE for another OS.

This Lab is intended to be trial and error so that during the session students should understand really what is behind the tool, instead of blindly following instructions, which never teach people anything IMHO. You've been warned ;-)

Expected duration : 180 minutes

Reference documents

When dealing with the installation and configuration of Project-Builder.org, the first approach is to look at the reference Web site http://trac.project-builder.org:

The netperf example is the most up to date introduction document at http://trac.project-builder.org/wiki/NetPerfExample as well as man page for pb.

A bootstrap page has been contributed by Bryan Gartner at: http://trac.project-builder.org/wiki/Bootstrapping

All the documentation is provided currently under a wiki format, so contributors are welcome and expected, including those finding issues in that training material. Trac also provides a bug report/enhancement request feature ;-)

A mailing-list dealing with pb is available at http://mondorescue.org/sympa/arc/pb-devel

Estimated time for the lab is placed in front of each part.

Environment setup

Estimated time: 15 minutes

Project-builder.org installation

Project-Builder.org is available externaly from ftp://ftp.project-builder.org/ and internally on the HP LAN from http://eurolinux.gre.hp.com/pub/linux/mondorescue/ or using ftp as well from the same place. An SVN access is also available, Cf the Wiki.

Version 0.11.2 is the current stable release. Version devel is the development version

As we'll work on a RHEL environment for the Lab, you may want to use yum to do the installation. For that, download the file under `rhel/6` named `pb.repo` and place it under your `/etc/yum.repos.d` directory. Of course, you can use rpm and deal with the dependencies yourself ;-)

You may also need for RHEL additional packages not provided in the base distribution, but which are brought by RPMforge (or EPEL). This is useful if you intend to build from upstream tar files e.g. So create the following file (adapting it tp your arch and distribution version):

```
# cd /etc/yum.repos.d/

# wget ftp://ftp.project-builder.org/rhel/6/x86_64/pb.repo

# cat > /etc/yum.repos.d/rpmforge.repo << EOF

[rpmforge]

name = Red Hat Enterprise $releasever - RPMforge.net - dag

baseurl = ftp://eurolinux.gre.hp.com/pub/linux/rpmforge/redhat/el6/en

enabled = 1

gpgcheck = 0

EOF
```

Or alternatively outside the HP LAN, replace the baeseurl line by:

```
# baseurl = http://apt.sw.be/redhat/el6/en/x86_64/dag/
```

Then use `yum` to install the application with all its dependencies:

```
# yum install project-builder
```

Other distributions may be easier to deal with by providing more packages out of the box (Case of most non-commercial distributions such as Debian/Ubuntu, Fedora, Mandriva, OpenSuSE, …)

Check that the correct version is installed and operational:

```
# pb --version

Option version requires an argument

pb (aka project-builder.org) Version 0.11.2-1250

Usage:

    pb [-vhSq][-r pbroot][-p project][[-s script -a account -P port][-t
os-ver-arch][-m os-ver-arch[,...]]]][-g][-i iso] <action> [<pkg1> ...]

    pb [--verbose][--help][--man][--quiet][--snapshot][--revision pbroot]
[--project project][[--script script --account account --port port][--
target os-ver-arch][--machine os-ver-arcg[,...]]]][--nographic][--iso iso]
<action> [<pkg1> …]
```

Local subversion setup

In order to be able to manage you build environment in configuration, we will use a local subversion repository on your machine. If not installed, please install subversion server and client, and create a local repository to manage your local modifications and allow its usage.

```
# yum --disablerepo=rpmforge install subversion.x86_64

# mkdir -p /prj

# svnadmin create /prj/svn

# ls /prj/svn

conf  db  format  hooks  locks  README.txt

# cat >> /prj/svn/conf/authz << EOF

[/]

pblab = rw

* = r

EOF

# cat >> /prj/svn/conf/passwd << EOF
```

```
[users]

pblab = pblab

EOF

# cat > /prj/svn/conf/svnserve.conf << EOF

[general]

password-db = passwd

authz-db = authz

[sasl]

EOF

# svnserve -d -r /prj/svn
```

The remaining operations should be done as user `pblab`, as no root access is needed in general for pb to operate. Create It with `adduser` and the passwd you want.

Check that you can log in this account and that the directory is nearly empty:

```
# su - pblab

$ ls -a

.   ..   .bash_logout   .bash_profile   .bashrc
```

As of now this document will use the name of the command (`pb`) to describe the project for easier reading, and because of the writer lazyness.

Using pb with an existing project (tar)

Estimated time: 45 minutes.

Pb setup

The goal of this part is to setup the minimal environment needed by project-builder.org to work correctly with a project whose delivery is accessible through a tar file. In this example we will use the afio project. Feel free to test with another one, the instructors during the lab should be able to adapt ;-)

First to work correctly the pb command needs to find the required information to the project you want to deal with in a configuration file under your home directly called .pbrc.

You can try to first launch pb with one of the recognized commands in order to see what happens:

```
$ pb clean

No existing /home/pblab/.pbrc found, creating one as template

No pbconfurl defined for unknown at
/usr/lib/perl5/vendor_perl/5.8.8/ProjectBuilder/Conf.pm line 325.

[pblab@o185i225 ~]$
```

```
[pblab@o185i225 ~]$ ls -a

.   ..   .bash_logout   .bash_profile   .bashrc   .pbrc
```

So, first you can remark that there are some errors ;-)

But more importantly, pb has created for you a template of configuration file under your home directory to help you start with its usage. Look at it:

```
[pblab@o185i225 ~]$ cat .pbrc

#

# Define for each project the URL of its pbconf repository

# No default option allowed here as they need to be all different

#

#pbconfurl example =
svn+ssh://svn.example.org/svn/pb/projects/example/pbconf

#pbconfurl pb = svn+ssh://svn.project-builder.org/mondo/svn/pb/pbconf

# Under that dir will take place everything related to pb

# If you want to use VMs/chroot/..., then use $ENV{'HOME'} to make it
portable

# to your VMs/chroot/...

# if not defined then /var/cache

#pbdefdir default = $ENV{'HOME'}/pb/projects

#pbdefdir pb = $ENV{'HOME'}

# If not defined, pbconfdir is under pbdefdir/pbproj/pbconf

#pbconfdir pb = $ENV{'HOME'}/pb/pbconf

# If not defined, pbprojdir is under pbdefdir/pbproj

# Only defined if we have access to the dev of the project

#pbprojdir example = $ENV{'HOME'}/example/svn

# We have commit acces to these

#pburl example =
cvs+ssh://user@example.cvs.sourceforge.net:/cvsroot/example

#pburl pb = svn+ssh://svn.project-builder.org/mondo/svn/pb
```

```
# I mask my real login on the ssh machines here

#sshlogin example = user

# where to find Build System infos:

#vmpath default = /home/qemu

#vepath default = /home/rpmbootstrap

#rmpath default = /home/remote

# Overwrite generic setup

#vmport pb = 2223

#vmport example = 2224
```

pb repository setup

Adapt the file in order to prepare your environment for a pb build of afio, and create the
directory that will host your local SVN export content:

```
[pblab@o185i225 ~]$ grep -Ev '^$|^#' .pbrc

pbconfurl afio = svn://localhost/pb/afio/pbconf

pbdefdir default = $ENV{'HOME'}/pb

[pblab@o185i225 ~]$ mkdir pb

[pblab@o185i225 pb]$ svn import pb svn://localhost/pb -m "Initial creation
of pb repo"

[...]

Committed revision 1.

[pblab@o185i225 ~]$ svn log -v svn://localhost/

------------------------------------------------------------------------

r1 | pblab | 2011-03-11 15:34:59 +0100 (Fri, 11 Mar 2011) | 1 line

Changed paths:

   A /pb

Initial creation of pb repo

------------------------------------------------------------------------

[pblab@o185i225 ~]$ cd pb
```

```
[pblab@o185i225 pb]$ ls -a

.  ..

[pblab@o185i225 pb]$ svn co svn://localhost/pb .

Checked out revision 1.

[pblab@o185i225 pb]$ ls -a

.  ..  .svn
```

Now that you have a correct SVN structure in your environment; you may try to ask pb to create the project structure of the afio packaging project for you, and start exploring it. As you only have a single package to create, you may call it afio and pass it as a parameter to your creation command:

```
[pblab@o185i225 pb]$ pb -p afio newproj afio

Adding /home/pblab/pb/afio to VCS ... OK

Updating /home/pblab/pb/afio ... OK

Adding /home/pblab/pb/afio/pbconf to VCS ... OK

Updating /home/pblab/pb/afio/pbconf ... OK

Checking in /home/pblab/pb/afio ... OK

Updating /home/pblab/pb/afio ... OK

Project: afio

Action: newproj
```

Look at what pb has created for you under that directory:

```
[pblab@o185i225 pb]$ ls -R

.:

afio

./afio:

build  delivery  pbconf

./afio/build:

./afio/delivery:

./afio/pbconf:

afio  afio.pb  pbfilter
```

```
./afio/pbconf/afio:

deb  pbfilter  pkg  rpm

./afio/pbconf/afio/deb:

afio.dirs  afio.docs  changelog  compat  control  copyright  rules

./afio/pbconf/afio/pbfilter:

./afio/pbconf/afio/pkg:

depend  pbbuild  pkginfo

./afio/pbconf/afio/rpm:

afio.spec

./afio/pbconf/pbfilter:

all.pbf          debian-5.0.pbf  fedora-1.pbf  fedora-3.pbf  fedora-5.pbf
fedora-7.pbf  md.pbf          pkg.pbf

debian-4.0.pbf  deb.pbf         fedora-2.pbf  fedora-4.pbf  fedora-6.pbf
fedora.pbf      novell.pbf  rpm.pbf
```

3 main directories have been created: `build` that will host all local build of packages, `delivery` that will contain the tar files generated as input for the build, and `pbconf` which contains all the metadata to build the packages.

The main configuration file for pb with this project is `./afio/pbconf/afio.pb`. We will have to modify it, in order for pb to have the required info on the afio project. We will do more modifications as we progress towards the knowledge of pb.

As we are on a rpm based distribution, we will have a look at the spec file generated `./afio/pbconf/afio/rpm/afio.spec`. You can also see that template for deb (Debian and Ubuntu) and pkg (Solaris/OpenSolaris) build have been generated as well. Also a `pbfilter` directory has been created to host macro filtering.

Tar file creation

If at that point, without doing any modification, we try to generate at least the tar files of the project, the result is:

```
[pblab@o185i225 pb]$ pb -p afio sbx2build

No defpkgdir defined for afio at
/usr/share/perl5/vendor_perl/ProjectBuilder/Conf.pm line 325.
```

```
[pblab@o185i225 pb]$ pbg defpkgdir

./afio/pbconf/afio.pb:#defpkgdir afio = dir-afio

./afio/pbconf/afio.pb:# Files are mentioned relatively to pbroot/defpkgdir
```

So time to give some content to our conf file:

```
[pblab@o185i225 pb]$ cat >> ./afio/pbconf/afio.pb << EOF

defpkgdir afio = dummy

EOF
```

In the case of a project for which you don't own/contribute to the development, the defpkgdir parameter value is useless, but however mandatory. If you have a local repository for the development, it should correspond to the name of the directory hosting the related development of the corresponding package.

```
[pblab@o185i225 pb]$ pb -p afio sbx2build

No pbpackager defined for afio at
/usr/share/perl5/vendor_perl/ProjectBuilder/Conf.pm line 325.
```

pbpackager is another mandatory tag. It indicates who is doing the job of packaging. You want to be rewarded no ? So indicate it: Here you have 2 choices: you can put it in the configuration file of the project, as done previously, or you can put it in your own .pbrc file which relates to all your activities. As this is a fairly generic parameter in that case, we opt for the second and associate that parameter to all projects, by using the default project name:

```
[pblab@o185i225 pb]$ cat >> $HOME/.pbrc << EOF

pbpackager default = Big Chief <bigchief@hp.com>

EOF
```

So with this, you can remark that there is a notion of inheritance of parameters from the most generic configuration file, up to the most specialized. The order being /etc/pb/pb.conf, $HOME/.pbc, project.pb, VEPath/.pbrc, VMPath/.pbrc, RMPath/.pbrc. New test:

```
[pblab@o185i225 pb]$ pb -p afio sbx2build

No projver defined for afio at
/usr/share/perl5/vendor_perl/ProjectBuilder/Conf.pm line 325.
```

Again, a new required parameter is needed. We have to provide the version of the project. Here we are packaging version 2.5 of the project:

```
[pblab@o185i225 pb]$ cat >> ./afio/pbconf/afio.pb << EOF

projver afio = 2.5

EOF
```

Each project should have a version, which will be used as the default version for every package produced. This can be overloaded if needed package by package. New test:

```
[pblab@o185i225 pb]$ pb -p afio sbx2build

No projtag defined for afio at
/usr/share/perl5/vendor_perl/ProjectBuilder/Conf.pm line 325.
```

Same story with the tag that needs to be provided to packages. A tag indicates the iteration level of build of a similar content, or said differently a fix on a build process.

```
[pblab@o185i225 pb]$ cat >> ./afio/pbconf/afio.pb << EOF

projtag afio = 1

EOF
```

In a future version, we may consider defaulting to 1. That's not the case yet. Start over again:

```
[pblab@o185i225 pb]$ pb -p afio sbx2build

Project: afio

Action: sbx2build

Packages: afio

No pburl defined for afio at
/usr/share/perl5/vendor_perl/ProjectBuilder/Conf.pm line 325.
```

So we made some progress, as the trace indicates and we have passed the first round of metadata really required by pb to work on our project. Of course, the next request is legitimate. We have not said yet where the software is ! So do it:

```
[pblab@o185i225 pb]$ cat >> ./afio/pbconf/afio.pb << EOF

pburl afio = ftp://ftp.project-builder.org/src/afio-2.5.tar.gz

EOF
```

Some comments here: there are multiple possibilities to designate the target we want to package. Here we use the simplest one, which is a pointer to a tar file (pb can use ftp or http or file protocols to access the file, and knows how to handle compressed tar files. But it can also target VCS (Version Control System) such as Subversion, SVK, CVS, Git or Mercurial using direct or ssh encapsulated protocol. We will illustrate it on another section.

So test again !

```
[pblab@o185i225 pb]$ pb -p afio sbx2build

Project: afio

Action: sbx2build

Packages: afio

No pbrepo defined for afio at
/usr/share/perl5/vendor_perl/ProjectBuilder/Conf.pm line 325.
```

Again that parameter seems to appear early as a question with regards to where we are in the build process. But it may be used for filtering possibilities that we will explore later on. It corresponds to the root URL of the final place where your users will find your packages and

deliveries, and is used to document some entries in build files, such as the spec file, thus needed quite early. Here give the name of where we found the source file:

```
[pblab@o185i225 pb]$ cat >> ./afio/pbconf/afio.pb << EOF

pbrepo afio = ftp://ftp.project-builder.org

EOF
```

Once more:

```
[pblab@o185i225 pb]$ pb -p afio sbx2build

Project: afio

Action: sbx2build

Packages: afio

Management of afio 2.5-0.20110311154738 (rev flat)

Downloading ftp://ftp.project-builder.org/src/afio-2.5.tar.gz with

2.5.tar.gz

Creating pbconf tar files compressed... OK

Under /home/pblab/pb/afio/delivery/afio-2.5.pbconf.tar.gz
```

Hurray ! We have at least produced something from pb. Well you could be doubtful it's easier and quicker than using traditional way, and up to that point, I agree with you. Except that this setup phase just needs to be done once.

Dealing with filters

So pb has downloaded the tar file for us, extracted it and generated 2 new tar files. In fact the first tar file is even not touched ("Preserving original tar file") in order to satisfy md5sum checks, e.g. This is only true because we deal with a tar based project. The second tar file contains all the metadata needed to build the package for our native platform. You can check its content:

```
[pblab@o185i225 pb]$ tar xvfz /home/pblab/pb/afio/delivery/afio-
2.5.pbconf.tar.gz

afio-2.5/pbconf/

afio-2.5/pbconf/rhel-6-x86_64/

afio-2.5/pbconf/rhel-6-x86_64/afio.spec

[pblab@o185i225 pb]$ more afio-2.5/pbconf/rhel-6-x86_64/afio.spec

PBLOG
```

As we can see in this file, there are some PB macros (PBLIC, PBGRP, …) that will probably cause an error when trying to build the rpm. If we compare that generated file by pb with the template created earlier here are the differences:

```
[pblab@o185i225 pb]$ diff  afio-2.5/pbconf/rhel-6-x86_64/afio.spec
afio/pbconf/afio/rpm/afio.spec

5c5

16c16

< Source:         ftp://ftp.project-builder.org/test/PBSRC

---

> Source:         PBREPO/PBSRC
```

We can see that some of the macro in the template have already been translated into their metadata content, but not all of them. Because again pb needs our help to have additional information before being able to process it. So we need to edit the main filter file `all.pbf` in the `pbfilter` directory in order to add the adequate content missing in the spec template:

```
[pblab@o185i225 pb]$ grep PB afio-2.5/pbconf/rhel-6-x86_64/afio.spec

```

You can note in the PBDESC the usage of a perl variable $/ which means a line separator. It will be expanded by pb, as well as the other variables such as the one provided by the %pb hash.

All these metadata can be shared across distributions, so they are placed here. However, some are specific to some distributions, such as the way they name licenses, or put software in groups. So we also need to add content in a more specific filter:

```
[pblab@o185i225 pb]$ vi ./afio/pbconf/pbfilter/rpm.pbf

[ edition ]

[pblab@o185i225 pb]$ svn diff ./afio/pbconf/pbfilter/rpm.pbf

So now that our macros have been expanded, we can try to regenerate the spec file for our distribution, and see if this time pb replaces everything correctly. Please also remark that we have still not committed anything in our repository, even if we have differences. pb is able to use the current state of our checked out version, as you're using the sbx2xxx commands. Of course, if you want to use what is in the repository, use instead the cms2xxx similar commands. Also note that each time you modify files under pbconf, you have to restart from the sbx2 commands so that the filtering and processing occurs as expected.

```

Of course, if we try to go to the next step, it fails, because one last remaining set of modifications needs to be performed concerns the spec file itself. The way to generate the

binaries and files to be delivered differ from one application to another and pb can not guess it, even if it proposes something to you. In our case, afio doesn't use a configure script.

So we now have our first packages built with pb for afio. Time to take a coffee no ? (If you
don't have that result, check that you don't miss some packages ;-)

As you can see, you don't need to have a knowledge of building rpm, as pb deals with that
for you. What you do need to know is how the software is built, which are the files produced
as an output, and which are the metadata related to the project.

Also you have seen a new command sbx2pkg, which chains sbx2build (which produces tar
files from project) and build2pkg (which produces packages from tar files).

You can check your package and install it to verify it. Note that if `rpmlint` is available on
your system, pb will automatically call it at the end of the build.

```
[pblab@o185i225 pb]$ rpm -qlvp /home/pblab/pb/afio/build/RPMS/x86_64/afio-

Name       : afio                         Relocations: (not relocatable)

Version    : 2.5                                  Vendor: (none)
```

```
Release      : 0.20110311161419.rhel6      Build Date: Fri 11 Mar 2011
04:17:26 PM CET

Install Date: (not installed)             Build Host: localhost

Group        : Applications/Archiving     Source RPM: afio-2.5-
0.20110311161419.rhel6.src.rpm

Size         : 155908                          License: Afio

Signature    : (none)

Packager     : Big Chief <bigchief@hp.com>

URL          : http://www.boutell.com/lsm/lsmbyid.cgi/000462

Summary      : afio is a cpio compatible archiver with extended features

Description :

afio is a cpio compatible archiver with extended features

It can compress on a file by file basis.
```

It could also be a good time now to commit our changes in our SVN repository (hint: `svn ci`)

Building for another distribution

Estimated time: 45 minutes.

By using an existing rpm based distribution VM

Setup of the VM

You can get the prepared VM at ftp://eurolinux.gre.hp.com/pub/linux/qemu/fedora-10-i386.qemu (Only valid inside the HP LAN). Or create one with `pb newvm` pointing to an ISO image of the distribution . Create a new directory to host this VM. Also install KVM on your system as root.

```
[pblab@o185i225 pb]$ mkdir $HOME/vm

[pblab@o185i225 pb]$ cd $HOME/vm

[pblab@o185i225 vm]$ lftp  ftp://eurolinux.gre.hp.com/pub/linux/qemu

cd ok, cwd=/pub/linux/qemu

lftp eurolinux.gre.hp.com:/pub/linux/qemu> get fedora-10-i386.qemu

3752185856 bytes transferred in 325 seconds (11.00M/s)

lftp eurolinux.gre.hp.com:/pub/linux/qemu> quit

# yum install kvm
```

Now that we have a working package for an rpm based distribution, it's easy to make another one for another rpm based one.

```
[pblab@o185i225 pb]$ pb -p afio -m fedora-10-i386 launchvm

Project: afio

Action: launchvm

No vmtype defined for afio at
/usr/lib/perl5/vendor_perl/5.8.8/ProjectBuilder/Conf.pm line 312.
```

So we're back to a known problem (except if you have done previous part which already solved it). Pb needs again some parameters in order to make the work for us. First it needs the type of VM that we are dealing with. In our case we want a KVM one whose type is kvm (qemu is also supported and more could be added). As pb will need more content to deal with VM, it will be detailed right now, instead of step by step. Also the location of those parameters will be in a dedicated configuration file that we will place alongside the VMs themselves. So we will first create a new directory to host our VMs, let pb know it through our main `.pbrc`, and create another `.pbrc` conf file in it to store the parameters linked to VM management:

```
[pblab@o185i225 pb]$ cat >> $HOME/.pbrc << EOF

vmpath default = /home/pblab/vm

EOF

[pblab@o185i225 pb]$ cat >> $HOME/vm/.pbrc << EOF

vmtype default = kvm

vmsize default = 7G

vmhost default = localhost

vmport afio = 2222

vmlogin default = pb

vmntp default = 0.pool.ntp.org

vmmonport default = 4444

vmlist default = fedora-10-i386,debian-5.0-i386

EOF
```

Some explanations. The vmpath parameter is global, and points to the directory where VMs will be created and used. Then in that directory, pb will load a .pbrc file if it finds it, in which are parameters related to the type of VMs we deal with in here.

The vmsize parameter is used at creation to give the size of the VM container. The vmhost, vmport and vmlogin parameters indicate how the host will communicate with the guest by ssh, using a port redirection to the vmport port on localhost of the ssh (22) port in the VM, and it will log on the VM using the pb account. The vmntp indicates where is the NTP server (as for builing software there is a strong need to have a good time synchronization). The vmmonport is the port used for monitoring the VM (planned usage for snapshot VM feature). And the vmlist last parameter indicate separated by comas, the list of all VM for which pb will be able to build in the format distribution_name-version-architecture.

pb has the capability to detect automatically on which system it runs, and adapt itself to that context. You can have more information on this by doing:

```
[pblab@o185i225 pb]$ pbdistrocheck

Project-Builder tuple:

OS:      linux

Name:    rhel

Ver:     6

Arch:    x86_64

Type:    rpm

Family: rh

Suffix: .rhel6

Update: sudo /usr/bin/yum clean all; sudo /usr/bin/yum -y update

Install:        sudo /usr/bin/yum clean all; sudo /usr/bin/yum -y update ;
sudo /usr/bin/yum -y install
```

This commands outputs details for pb of the underlying distribution: its name, version, tag name, build type, package extension, update command and architecture. If you disagree with the choices made by pb, nothing more simple than to adapt it to your needs, or to add support for a new distribution. Edit the `/etc/pb/pb.conf` file and give feedback !

So now pb is aware of how to deal with VMs, try again to launch it:

```
[pblab@o185i228 vm]$ pb -p afio -m fedora-10-i386 launchvm

Project: afio

Action: launchvm

Launching the VM /home/pblab/vm/fedora-10-i386.qemu... OK

Waiting 120 s for VM fedora-10-i386 to come up... open /dev/kvm: No such
file or directory

Could not initialize KVM, will disable KVM support

OK

VM /home/pblab/vm/fedora-10-i386.qemu launched (pid 8834)
```

You VM may or not come up correctly. Typically KVM launches the VM with only 128 MB of RAM, which may not be sufficient for the distribution you deal with. pb allows you adapt it in 2 ways. One is in the above mentioned configuration file:

```
[pblab@o185i228 vm]$ cat >> $HOME/vm/.pbrc << EOF

vmopt default = -m 384 -daemonize

EOF
```

Which is the most suited when the modification is permanent. Please note that the parameter for vmopt is the name of a distribution, from the most precise tuple definition to the least. So you can have a `vmopt fedora-11-i386`, a `vmopt fedora-11` a `vmopt fedora`, as well as for the distribution family (`vmopt rh`) or type (`vmopt rpm`). Useful for inheritance purposes.

Now if you just want to change the execution of the instance of VM you're about to start, you can also use the `PBVMOPT` environment variable for this, in addition to the previous parameters. For example, if you just want the VM to start without X-Window interface as you're remote on a serial line, you can use the following:

```
[pblab@o185i228 vm]$ export PBVMOPT="-nographic"
```

that way the VM will be lauched both with `-m 284 -daemonize -nographic`.

Same way if you want to use a VNC redirection if you're on Windows as a client without cygwin and X11 installed locally.

Relaunch the VM and check that you can have access to with with ssh (account root/linux1). The configuration done on ssh avoids painful authentication messages on the validity of localhost (accessed in fact here with anther machine than the regular localhost).

```
[pblab@o185i228 vm]$ pb -p afio -m fedora-10-i386 launchvm

Project: afio

Action: launchvm

Launching the VM /home/pblab/vm/fedora-10-i386.qemu... OK

Waiting 120 s for VM fedora-10-i386 to come up... open /dev/kvm: No such
file or directory

Could not initialize KVM, will disable KVM support

OK

VM /home/pblab/vm/fedora-10-i386.qemu launched (pid 8938)

[pblab@o185i228 vm]$ cat >> $HOME/.ssh/config << EOF

host localhost

    StrictHostKeyChecking no

EOF

[pblab@o185i228 vm]$ ssh -p 2222 root@localhost

The authenticity of host 'localhost (127.0.0.1)' can't be established.

RSA key fingerprint is f4:36:92:96:9e:a1:b6:ff:5f:aa:4e:d9:af:94:5c:b3.

Are you sure you want to continue connecting (yes/no)? yes

Warning: Permanently added 'localhost' (RSA) to the list of known hosts.

root@localhost's password:

Last login: Sun Jan 25 12:02:51 2009
```

```
[root@localhost ~]# pb --version

Option version requires an argument

pb (aka project-builder.org) Version 0.11.2-1250

Usage:

    pb [-vhSq][-r pbroot][-p project][[-s script -a account -P port][-m

    mach-1[,...]]][-i iso] <action> [<pkg1> ...]

    pb [--verbose][--help][--man][--quiet][--snapshot][--revision

    pbroot][--project project][[--script script --account account --port

    port][--machine mach-1[,...]]][--iso iso] <action> [<pkg1> …]

[root@localhost ~]# ^D
```

Looks fine,. Now you can try to use it to build packages for Fedora 10 i386, after solving yet some additional requested parameters, and updating the VM with the latest pb version, as well as using the current context (ssh keys). Also on the HP LAN a proxy will need to be defined (pb will propagate it in the VM as needed).

```
[pblab@o185i228 vm]$ cat >> $HOME/vm/.pbrc << EOF

vmntpcmd default = /usr/sbin/ntpdate

vmtmout default = 180

EOF

```

So we now have fedora 10 packages ! You can look at them locally under `/home/pblab/pb/afio/build/fedora/10/`. We have had to add `vmntpcmd` paramater to our configuration file to indicate which command should be used to synchronize the VM for time aspects. As well the `vmtmout` parameter gives to pb the time to wait in seconds before trying to dialog with the VM (boot time) if it has to launch it (which wasn't our case). That timeout can be drastically reduced if you use the snapshot feature of the VM (can be done manually with pb, and is being added automatically in the devel version). These 2 parameters use as well distribution_name-version-architecture as a key.

Then we have to setup a proxy because we will download in `setupvm` packages from CPAN to resolve pb dependencies. On the HP LAN we need that proxy in order for our download to succeed. The `setupvm` phase is required here for 2 reasons. One is to update pb in the VM at the same version as the one we used locally, for coherency. The second is to create dedicated SSH keys for further exchanges with the pb and the root accounts inside the VM. The pb account in the VM is used to launch all pb related activities, and has to be declared for pb to work with VMs at all. It has o be noted that this is a case where pb install itself in the VM under a tar format, to manage the chicken and egg problem. To avoid any issue, do not install pb as a package in the VM in parallel.

Then we invoked `sbx2vm` which first does the `sbx2build` phase and then send in the VM all the required tar balls, configuration files and one script to launch pb in the VM, doing the right setup and invoking in it the `build2pkg` phase we have done previously locally.

Of course, pb still could do more providing we give it some more info. Just do it:

Setup of a delivery environement

```
[pblab@o185i228 vm]$ cat >> $HOME/pb/afio/pbconf/afio.pb << EOF

sshhost afio = localhost

sshlogin afio = delivery

sshdir afio = /var/ftp/pub/afio

sshport afio = 22

EOF
```

Here we define where to deliver our built packages: the machine (sshhost), the account used to log on it through ssh (sshlogin), the directory (sshdir) in which we will setup the repository and the port on which ssh is working on that system (sshport)

PLEASE NOTE that no security is considered here (no pass phrase for ssh accounts). This should be considered for production environments.

And as root:

```
[root@o185i228 home]# yum install vsftpd createrepo

[root@o185i228 home]# /etc/init.d/vsftpd start

Starting vsftpd for vsftpd:                              [  OK  ]

[root@o185i228 home]# chkconfig vsftpd on

[root@o185i228 home]# wget ftp://fr2.rpmfind.net/linux/epel/6/x86_64/yum-
arch-2.2.2-9.el6.noarch.rpm

[root@o185i228 home]# rpm -Uvh yum-arch-2.2.2-9.el6.noarch.rpm

[root@o185i228 home]# useradd delivery

[root@o185i228 home]# perl -pi -e 's/delivery:!!/delivery:*/' /etc/shadow

[root@o185i228 home]# mkdir ~delivery/.ssh

[root@o185i228 home]# chmod 700  ~delivery/.ssh

[root@o185i228 home]# cp ~pblab/.ssh/pb_dsa.pub
~delivery/.ssh/authorized_keys

[root@o185i228 home]# chmod 600  ~delivery/.ssh/authorized_keys

[root@o185i228 home]# chown -R delivery ~delivery/.ssh

[root@o185i228 home]# mkdir -p /var/ftp/pub/afio

[root@o185i228 home]# chown -R delivery /var/ftp/pub/afio
```

We install newly needed packages to provide ftp acces (and set it up) and yum repository management. We also create an account having the rights to manage the afio ftp zone, and able to receive our updates by ssh.

Check that you can access the newly created account with ssh without password, and then launch the build again:

```
[pblab@o185i228 vm]$ ssh -i ~/.ssh/pb_dsa delivery@localhost touch
/var/ftp/pub/afio/README
```

Build in the VM

```
[pblab@o185i228 vm]$ pb -p afio -m fedora-10-i386 sbx2vm
```

So pb has prepared and delivered for us a repository for afio. It created a test subdirectory, as we are working on a test version (testver in the afio.pb configuration file). For a stable release it would have created the same structure directly at the sshdir point.

If we want to use the repo file locally to check everything works as expected, we have to do the same for our local build:

```
[pblab@o185i228 ~]$ pb -p afio sbx2pkg

Project: afio

Action: cms2pkg

Packages: afio

Management of afio 2.5-0.20091203125549 (rev flat)

Install      2 Package(s)

Update       0 Package(s)
```

```
Remove         0 Package(s)

Total download size: 139 k

Is this ok [y/N]:

Exiting on user Command

Complete!
```

We don't continue as we are not on the right architecture, but we can see our package in the list as expected.

Note that you can also deliver the tar sources using the `cms2ssh` command of pb.

By using an existing deb based distribution VM

Setup of the VM

You can get the prepared VM at ftp://eurolinux.gre.hp.com/pub/linux/qemu/debian-5.0-i386.qemu. (Only valid inside the HP LAN). Or create one with `pb newvm` pointing to an ISO image of the distribution .

```
[pblab@o185i225 pb]$ cd $HOME/vm

[pblab@o185i225 vm]$ lftp  ftp://eurolinux.gre.hp.com/pub/linux/qemu

cd ok, cwd=/pub/linux/qemu

lftp eurolinux.gre.hp.com:/pub/linux/qemu> get debian-5.0-i386.qemu
```

Building for another type of distribution is much more easy now with pb, as most of what we need is already there. We can concentrate on the build files specific to Debian distribution:

```
[pblab@o185i228 ~]$ pb -p afio -m debian-5.0-i386 setupvm

Project: afio

Action: setupvm

[…]

pb (aka project-builder.org) Version 0.11.1-1250

Usage:

    pb [-vhSq][-r pbroot][-p project][[-s script -a account -P port][-m

    mach-1[,...]]]][-i iso] <action> [<pkg1> ...]

[pblab@o185i228 ~]$ pb -p afio -m debian-5.0-i386 sbx2vm
```

```

./pbscript: line 10: dpkg-scansources: command not found
```

OK, so as expected, it can not working magically. Even if some read HP as Harry Potter ;-)

A specificity of Debian is that it needs a working changelog, in order to determine metadata correctly. Pb can help building a sensible changelog for Debian (as well as for rpm packages).

Also if we want to be able to build a local Debian repository, we will need an additional application (dpkg-scanpackages). There is no native package for RHEL 5, so we will use the package currently in Mandriva, which is compatible (why do you think I'm commiter for it ;-):

```
[root@o185i228 home]# wget
ftp://fr2.rpmfind.net/linux/dag/redhat/el5/en/i386/dag/RPMS/po4a-0.33.2-
1.el5.rf.noarch.rpm

[root@o185i228 home]# yum install perl-gettext

[root@o185i228 home]# rpm -Uvh po4a-0.33.2-1.el5.rf.noarch.rpm

[root@o185i228 home]# wget    http://ftp.u-
picardie.fr/mirror/ftp.mandriva.com/Mandrakelinux//mandrakelinux/official/
2010.0/SRPMS/contrib/release/dpkg-1.13.26-1mdv2010.0.src.rpm

[root@o185i228 home]# rpm -ivh  dpkg-1.13.26-1mdv2010.0.src.rpm

[root@o185i228 home]# perl -pi -e 's/%mkrel//'
/usr/src/redhat/SPECS/dpkg.spec

[root@o185i228 home]# perl -pi -e 's/%configure2_5x/%configure/'
/usr/src/redhat/SPECS/dpkg.spec

So there are fixes, due to typo (that have been fixed since in SVN of pb). The other adaptations are similar to the one done for building the RPM of afio: list of files/dirs to manage, and way to build the software.

Now time to generate our deb packages:

```
[pblab@o185i228 deb]$ pb -p afio -m debian-5.0-i386 cms2vm

Project: afio

Action: cms2vm

```

So we have built our deb package, and check its metadata and its content.

By creating a new VM

pb can also help you making new VM from scratch. Using LinuxCOE to design a Fedora install, we will build a QEMU/KVM VM hosting a Fedora release, set it up and build our afio package in it.

For this to work, you'll have to install at least a text based browser such as lynx on your RHEL 6 distribution and the KVM tool if not already done (you also may need xauth). Outside the HP LAN, refer to http://www.instalinux.com)

```
[pblab@o185i225 pb]$ lynx http://linuxcoe.corp.hp.com/designer

Choose Generate a boot floppy

Distro Rev Arch: OpenSUSE 11.1 - x86_64

Continue

Continue

Waystation: eurolinux.grenoble.hp.com - EMEA – Grenoble FR

Continue

Continue

Continue

Give passwd for root and a pblab user.

Go For It!

Download the ISO image generated

Save to disk as opensuse-11.1-x86_64-coe.iso

q

y
```

Now that you have designed your installation, use that ISO image as a boot image for your new VM with the help of pb:

```
[root@o185i228 home]# yum install kvm-qemu-img

[pblab@o185i228 ~]$ pb -p afio -i opensuse-11.1-x86_64-coe.iso -m
opensuse-11.1-x86_64 newvm

Project: afio

Action: newvm

Creating the QEMU VM... OK

Launching the VM /home/pblab/vm/opensuse-11.1-x86_64.qemu... OK

Waiting 180 s for VM opensuse-11.1-x86_64 to come up... open /dev/kvm: No
such file or directory

Could not initialize KVM, will disable KVM support

Please ensure that sshd is running in your VM by default

and that it allows remote root login (PermitRootLogin yes in
/etc/ssh/sshd_config)

# In the VM type install and during the installation do the next chapter.

# When it's done, log on the system and check the above items are valid.

[pblab@o185i228 ~]$ pb -p afio -m opensuse-11.1-x86_64 setupvm
```

```
Project: afio

Action: setupvm

Launching the VM /home/pblab/vm/opensuse-11.1-x86_64.qemu... OK

[...]
```

After the automatic providing of the VM with LinuxCOE, you just have to set it up with `setupvm`, and then you can add it to your list of VM to build for, and rapidly generate new afio packages for that distribution. On a slow system you may have to use `launchvm` to finish the setup before being able to use `setupvm`.

By creating a new RPM based VE

Estimated time: 45 minutes

Setup of the VE

You can create one with `pb newve`. Create a new directory to host this VE. Also install `rpmboostrap` on your system as root. If inside HP point to a local repository for Mandriva 2010.1 and install from sources to get the latest pb available and not the distribution one. Security is left open for the lab account.

```
[pblab@o185i225 pb]$ mkdir $HOME/ve

[pblab@o185i225 pb]$ cd $HOME/ve

# yum install rpmbootstrap

# perl -pi -e 's|http://mirrors.kernel.org/mandriva/|
http://eurolinux.gre.hp.com/pub/linux/mandriva/|' /etc/pb/pb.conf

# perl -pi -e 's|pbinstalltype default = pkg|pbinstalltype default =
file|' /etc/pb/pb.conf

# cat >> /etc/sudoers << EOF

pblab ALL=(ALL) NOPASSWD: ALL

EOF

[pblab@o185i225 pb]$ pb -p afio -m mandriva-2010.1-x86_64 newve

Project: afio

Action: newve

No vetype defined for afio at
/usr/share/perl5/vendor_perl/ProjectBuilder/Conf.pm line 325.
```

So we're back to a known problem (except if you have done previous part which already solved it). Pb needs again some parameters in order to make the work for us. First it needs the type of VE that we are dealing with. In our case we want a rpmbootstrap one whose type is chroot + rpmtype rpmbootstrap (rinse and mock are also supported and more could be added, as well as debootstrap for deb based distributions). As pb will need more content to deal with VE, it will be detailed right now, instead of step by step. Also the location of those parameters will be in a dedicated configuration file that we will place alongside the VEs

themselves. So as we have first created a new directory to host our VEs, we will let pb know it through our main .pbrc, and create another .pbrc conf file in it to store the parameters linked to VE management:

```
[pblab@o185i225 pb]$ cat >> $HOME/.pbrc << EOF

vepath default = /home/pblab

EOF

[pblab@o185i225 pb]$ cat >> $HOME/ve/.pbrc << EOF

vetype default = chroot

verpmtype default = rpmbootstrap

vedebtype default = debootstrap

verebuild default = false

ventp default = 1.pool.ntp.org

ventpcmd default = /usr/sbin/ntpdate

veopt default =

vesnap default = false

velogin default = pblab

velist default = mandriva-2010.1-x86_64

EOF
```

Some explanations. The vepath parameter is global, and points to the directory where VEs will be created and used. Then in that directory, pb will load a .pbrc file if it finds it, in which are parameters related to the type of VEs we deal with in here.

The verpmtype and vedebtype parameters are used to indicate which tool is used to create the chroot environment. The verebuild parameter is used to force the systematic recreation of the VE or not at build time. The ventp and ventpcmd parameters indicate where is the NTP server and how to synchronize with it (as for builing software there is a strong need to have a good time synchronization). The veopt parameter allows to pass options to the command creating the chroot. The vesnap parameter is used to indicate whether we want to snapshot the VE at the end of the build (cretaing a compressed tar of it) tin order to restart from that if needed. The velogin is here to define the account under which the build process will occur. And the velist last parameter indicates separated by comas, the list of all VE for which pb will be able to build in the format distribution_name-version-architecture.

So time to relaunch our command. This time it should work, but may take a bit of time.

```
[pblab@o185i228 vm]$ pb -p afio -m mandriva-2010.1-x86_64 newve

```

So we now have Mandriva 2010.1 packages ! You can look at them locally under
/home/pblab/pb/afio/build/mandriva/2010.1/. The setupve phase is required
here for 2 reasons. One is to update pb in the VE to the same version as the one we used
locally, for coherency. The second is to create dedicated SSH keys for further exchanges
with the pblab and the root accounts inside the VE. The pblab account in the VE is used to
launch all pb related activities, and has to be declared for pb to work with VEs at all. It has
to be noted that this is a case where pb install itself in the VE under a tar format, to manage
the chicken and egg problem. To avoid any issue, do not install pb as a package in the VE in
parallel.

Then we invoked sbx2ve which first does the sbx2build phase and then send in the VE all
the required tar balls, configuration files and one script to launch pb in the VE, doing the
right setup and invoking in it the build2pkg phase we have done previously locally.

Of course, pb still could do more providing we give it some more info. Please refer to the
paragraph "Setup of a delivery environement", page 37, to know how to set it up as this is
similar as what we did for VM.

Build in the VE

```
[pblab@o185i228 vm]$ pb -p afio -m mandriva-2010.1-x86_64 build2ve

So pb has prepared and delivered for us a repository for afio. It created a test subdirectory, as we are working on a test version (testver in the afio.pb configuration file). For a stable release it would have created the same structure directly at the sshdir point.

Of course at the end it tries to also generate indices for Mandriva, but some commands do not exist on RHEL so it fails. It's left as an exercice to the reader to fix that part.

If we want to use the repo file locally to check everything works as expected, we have to do the same for our local build:

```
[pblab@o185i225 pb]$ perl -pi -e 's|pbrepo afio = ftp://ftp.project-
builder.org|pbrepo afio = ftp://localhost/pub/afio|'
~/pb/afio/pbconf/afio.pb

[pblab@o185i228 ~]$ pb -p afio sbx2pkg

Project: afio

Action: sbx2pkg

Packages: afio
```

```

Note that you can also deliver the tar sources using the `sbx2ssh` command of pb.

By using a deb based distribution VE

Setup of the VE

Setup has been previously done. However, a mandatory is needed to build a deb based VE: debootstrap. As it is not available out of the box on RHEL 6, use the one from Mandriva.

```
[pblab@o185i225 pb]$ wget
http://ftp.free.fr/mirrors/ftp.mandriva.com/MandrivaLinux/official/2010.1/
x86_64/media/contrib/release/debootstrap-1.0.19-1mdv2010.0.x86_64.rpm

[pblab@o185i225 pb]$ sudo rpm -Uvh debootstrap-1.0.19-
1mdv2010.0.x86_64.rpm

warning: debootstrap-1.0.19-1mdv2010.0.x86_64.rpm: Header V3 DSA/SHA1
Signature, key ID 78d019f5: NOKEY

Preparing...                    #########################################
[100%]

   1:debootstrap               #########################################
[100%]
```

Now type directly (and don't forget it takes time):

```
[pblab@o185i225 pb]$ pb -p afio -m debian-6.0-x86_64 newve

Project: afio

Action: newve

So pb has again prepared and delivered for us a repository for afio. Of course at the end it tries to also generate indices for Debian, but some commands do not exist on RHEL so it fails. It's left as an exercice to the reader to fix that part.

Using pb with an existing project (SVN)

Estimated time: 15 minutes.

pb setup

Now that we have done it once, it will be much quicker to adapt our setup to build for a new project. You just have to adapt the `.pbrc` file that way:

```
[pblab@o185i225 ~]$ cat >> $HOME/.pbrc << EOF

pbconfurl mondorescue =  svn+socks://svn.project-
builder.org/pb/projects/mondorescue/pbconf

EOF
```

And inside the HP LAN, setup a SVN proxy with tsocks:

```
[root@o185i228 home]# yum install tsocks

[root@o185i228 home]# cat > /etc/tsocks.conf << EOF

server = socks-server

local = 15.0.0.0/255.0.0.0

local = 16.0.0.0/255.0.0.0

EOF

[pblab@o185i225 ~]$ cat >> $HOME/.pbrc << EOF

pbsockscmd default = tsocks

EOF
```

pb repository setup

```
[pblab@o185i225 pb]$ pb -p mondorescue cms2pkg

Checking out svn://svn.project-builder.org/pb/projects/mondorescue/pbconf
to /home/pblab/pb/mondorescue/pbconf ... OK

ERROR: no pbroot defined, used /home/pblab/pb/mondorescue/pbconf, without
finding mondorescue.pb in it

      Please use -r release in order to be able to initialize your
environment correctly

Unable to open /home/pblab/pb/mondorescue/pbconf/mondorescue.pb at
/usr/lib/perl5/vendor_perl/5.8.8/ProjectBuilder/Env.pm line 1041.
```

Of course, we need to say which version we want to build. Try building the development one named branches/2.2.10. Remark also that pb extracted the whole pbconf content for mondorescue from the SVN.

```
[pblab@o185i225 pb]$ pb -p mondorescue -r branches/2.2.10 cms2pkg

Project: mondorescue

Action: cms2pkg

Packages: mondo,mindi

Checking out svn+ssh://svn.mondorescue.org/mondo/svn/mondorescue/2.2.10 to
/home/pblab/pb/mondorescue//branches/2.2.10 ... The authenticity of host
'svn.mondorescue.org (213.30.161.23)' can't be established.

RSA key fingerprint is 58:7f:66:05:4e:c1:b0:60:89:7a:b7:09:1c:10:18:5b.

Are you sure you want to continue connecting (yes/no)? yes

pblab@svn.mondorescue.org's password:
```

Of course, the setup of the project leader is different from us. He is using SSH to have SVN access, which is not our case. So we need to overload that configuration to have access to the project sources:

```
[pblab@o185i228 ~]$ grep svn
pb/mondorescue/pbconf/branches/2.2.10/mondorescue.pb

pburl mondorescue = svn+ssh://svn.mondorescue.org/mondo/svn/mondorescue

[pblab@o185i225 ~]$ cat >> $HOME/.pbrc << EOF

pburl mondorescue = svn+socks://svn.mondorescue.org/mondorescue/branches

EOF
```

Tar file and package creation

If at that point, without doing any modification, we try to generate at least the tar files of the project, the result is:

```
[pblab@o185i225 pb]$ pb -p mondorescue sbx2pkg

Project: mondorescue

Action: cms2pkg

Packages: mondo,mindi

Checking out svn://svn.mondorescue.org/mondorescue/branches/2.2.10 to
/home/pblab/pb/mondorescue//branches/2.2.10 ... OK

Management of mondo 2.2.10-0.20091204174124 (rev 2497)
```

```
Exporting /home/pblab/pb/mondorescue//branches/2.2.10/mondo from svn+socks
to /home/pblab/pb/mondorescue/delivery/mondo-2.2.10 ... OK

Installing dependencies (newt-devel libtool)...

We trust you have received the usual lecture from the local System

Administrator. It usually boils down to these three things:

    #1) Respect the privacy of others.

    #2) Think before you type.

    #3) With great power comes great responsibility.

Password:

[…]

error: Failed build dependencies:

        newt-devel >= 0.50 is needed by mondo-2.2.10-
0.20091204174124.rhel5.4.x86_64

        gcc-c++ is needed by mondo-2.2.10-0.20091204174124.rhel5.4.x86_64

        autoconf is needed by mondo-2.2.10-0.20091204174124.rhel5.4.x86_64

0.20091204174124.rhel5.4.noarch.rpm
```

Ok, so we were able to generate one of the 2 packages planned. The reason for the lack of success for mondo is linked to a lack of packages needed at build time. Some are part of the initialization of the project (automake and the likes) others are dependencies in RPM that pb tries unsuccessfully to install as our build account is not in the sudoers here (you may not want to adopt the solution below for obvious security reason). Fix these issues:

```
[root@o185i228 home]# yum install autoconf automake libtool ImageMagick
docbook-utils-pdf gcc-c++

[root@o185i228 home]# cat >> /etc/sudoers << EOF

pblab ALL=(ALL) ALL

EOF

[pblab@o185i228 ~]$ pb -p mondorescue -r branches/2.2.10 cms2pkg mondo

Project: mondorescue

@@ -57,6 +57,7 @@

 %setup -q

 %build

+mkdir m4

 %configure

 make %{?_smp_mflags} VERSION=%{version}
```

It could also be possible at that point to build for your existing VMs.

There is much more to discover around pb (management of patches, other DVCS, managing announces to mailing list, website, managing official vs test versions, …) but I leave that for an update of this document.
